

Final video script

Hi, I'm Hayk. During university I lived in seven cities over four years. I could track tasks, but not how one delay affected the rest. So I built the tool I wish I'd had: dependencies, not a checklist.

This example maps a Tokyo-to-San Francisco move around one hard deadline: I arrive October eighteenth, so I must be ready by the seventeenth.

Say Housing slips from the tenth to the twelfth. The tool asks what it can't know: how much time do I need for the address pack - zero, one, or two days?

I'll choose two. The pack and internet share the fourteenth, within my two-task cap, and check-in becomes an unconfirmed request for the fifteenth. I can compare options without losing my Housing change, review, apply, and undo. Editing a later task only affects what follows.

At first treated banking as independent of my address. I challenged that because location can affect branch choice. Since that varies, I kept the link as a reviewable hypothesis.

Final video script - continued

I brainstormed several directions with AI, then filtered them against the brief, Palantir's work, and my experience. I dropped Run Lens because without wearable data I'd be inventing evidence.

The first version was crowded and scripted: a preset seven-day delay, only Housing was editable, and the timeline didn't help. I replaced the simulation with direct date editing and forward-only propagation.

I caught Ready landing on the nineteenth after an eighteenth arrival, so the seventeenth became fixed. I added a way back from preview, made the timeline compare plans, removed extra branding, and applied the supplied design reference.

AI sped up exploration, implementation, and rule testing; I set the direction and challenged outputs that didn't hold up. The product uses explicit rules, not a live model.

Next I'd test it with movers and learn what trustworthy event creation needs.
